An agent that researches a small business, then re-checks every claim with code before a seller repeats it.

People who sell web services to small businesses research them first, more and more with AI. The agents repeat stale facts with confidence: "your site is down" when it loads, a previous owner's phone, a QR-menu page taken for the shop's website. One false sentence loses the call. Proofline's rule: **the model may propose, only evidence may decide.**

How a run works

1. Search
Tavily finds the business by name and city. The model may take a domain or phone only from these results.

2. Propose
Nemotron 3 Super picks who the business is and proposes claims from a fixed catalog, with reasons.

3. Prove
Code re-runs a check for every claim (DNS, HTTP, TLS, map, search). A claim that fails is dropped, in plain sight.

4. Explain
Nemotron 3 Nano writes one plain sentence per proven claim; a sentence that adds a number is rejected.

Measured on real Turkish small businesses, every kept claim checked by hand outside Proofline

96% 109 of 114
Kept claims right on the last four fresh lists (48 businesses the fixes were never made for)

98 → 62
Wrong claims a reader would see without the proof gate → with it, over all 19 rounds

4 of 48 reports
Reports with at least one wrong sentence on the last four fresh lists (5 without the gate)

67.5% → 92.9%
Claims proven with Tavily results, right: first rounds → last four fresh lists

8 of 10 sites
Same 12 businesses: own sites found with Tavily on; 2 of 10 with search off; the model alone made 0 claims

$0.002–0.004
Model cost of one recorded example run at Nebius list price, shown in every report

Nebius Token Factory and NVIDIA Nemotron: each model has one job, and code checks its answer

Role	Model	What code does with the answer
Planner, claim proposer, writer	nemotron-3-super-120b-a12b	A domain or phone not in the search results is removed; every claim goes to the gate; a finding with no proven citation is cut
Second opinion	Nemotron-3-Ultra-550b-a55b	Only when just a name is typed: the website pick stands only if Ultra picks the same site (wrong sites 14 → 10 of 46)
Owner rewrite	NVIDIA-Nemotron-3-Nano-30B-A3B	A rewrite that adds a number not in the evidence is rejected

Every call sends a strict JSON Schema whose enums come from the run itself. A model calls panel shows each call's model, latency, tokens, cost and outcome.

Try it in 30 seconds

- Open the demo and click the recorded example **Kuzey Kafe**.
- Watch the model take a QR-menu page for the café's site, and **the gate drop the three claims** made against it.
- Under any claim press **Re-run proof**: its checks run again, now. The interface is English and Turkish.

What it does not do

- It cannot know an **older or unrelated name**: a shop selling on a site with another name is told "no website of its own".
- A **bare one-word name** with no city is often "not settled" rather than guessed.
- The hand checks were done by the team, outside the tool. A frozen final list of 12 new businesses ran once on 27 Oct: **33 of 33** kept claims right.
